# DEVELOPING WITH GSSAPI

The GSSAPI (Generic Security Services API) allows applications to communicate securely using Kerberos 5 or other security mechanisms. We recommend using the GSSAPI (or a higher-level framework which encompasses GSSAPI, such as SASL) for secure network communication over using the `libkrb5` API directly.

GSSAPIv2 is specified in [RFC 2743](#) and [RFC 2744](#). This documentation will describe how various ways of using GSSAPI will behave with the `krb5` mechanism as implemented in MIT `krb5`, as well as `krb5`-specific extensions to the GSSAPI.

## 1.1 Name types

A GSSAPI application can name a local or remote entity by calling `gss_import_name`, specifying a name type and a value. The following name types are supported by the `krb5` mechanism:

- **GSS\_C\_NT\_HOSTBASED\_SERVICE**: The value should be a string of the form `service` or `service@hostname`. This is the most common way to name target services when initiating a security context, and is the most likely name type to work across multiple mechanisms.
- **GSS\_KRB5\_NT\_PRINCIPAL\_NAME**: The value should be a principal name string. This name type only works with the `krb5` mechanism, and is defined in the `<gssapi_krb5.h>` header.
- **GSS\_C\_NT\_USER\_NAME** or **GSS\_C\_NULL\_OID**: The value is treated as an unparsed principal name string, as above. These name types may work with mechanisms other than `krb5`, but will have different interpretations in those mechanisms. **GSS\_C\_NT\_USER\_NAME** is intended to be used with a local username, which will parse into a single-component principal in the default realm.
- **GSS\_C\_NT\_ANONYMOUS**: The value is ignored. The anonymous principal is used, allowing a client to authenticate to a server without asserting a particular identity (which may or may not be allowed by a particular server or Kerberos realm).
- **GSS\_C\_NT\_MACHINE\_UID\_NAME**: The value is `uid_t` object. On Unix-like systems, the username of the uid is looked up in the system user database and the resulting username is parsed as a principal name.
- **GSS\_C\_NT\_STRING\_UID\_NAME**: As above, but the value is a decimal string representation of the uid.
- **GSS\_C\_NT\_EXPORT\_NAME**: The value must be the result of a `gss_export_name` call.

## 1.2 Initiator credentials

A GSSAPI client application uses `gss_init_sec_context` to establish a security context. The *initiator\_cred\_handle* parameter determines what tickets are used to establish the connection. An application can either pass

**GSS\_C\_NO\_CREDENTIAL** to use the default client credential, or it can use `gss_acquire_cred` beforehand to acquire an initiator credential. The call to `gss_acquire_cred` may include a *desired\_name* parameter, or it may pass **GSS\_C\_NO\_NAME** if it does not have a specific name preference.

If the desired name for a krb5 initiator credential is a host-based name, it is converted to a principal name of the form *service/hostname* in the local realm, where *hostname* is the local hostname if not specified. The hostname will be canonicalized using forward name resolution, and possibly also using reverse name resolution depending on the value of the **rdns** variable in *libdefaults*.

If a desired name is specified in the call to `gss_acquire_cred`, the krb5 mechanism will attempt to find existing tickets for that client principal name in the default credential cache or collection. If the default cache type does not support a collection, and the default cache contains credentials for a different principal than the desired name, a **GSS\_S\_CRED\_UNAVAIL** error will be returned with a minor code indicating a mismatch.

If no existing tickets are available for the desired name, but the name has an entry in the default client *keytab\_definition*, the krb5 mechanism will acquire initial tickets for the name using the default client keytab.

If no desired name is specified, credential acquisition will be deferred until the credential is used in a call to `gss_init_sec_context` or `gss_inquire_cred`. If the call is to `gss_init_sec_context`, the target name will be used to choose a client principal name using the credential cache selection facility. (This facility might, for instance, try to choose existing tickets for a client principal in the same realm as the target service). If there are no existing tickets for the chosen principal, but it is present in the default client keytab, the krb5 mechanism will acquire initial tickets using the keytab.

If the target name cannot be used to select a client principal (because the credentials are used in a call to `gss_inquire_cred`), or if the credential cache selection facility cannot choose a principal for it, the default credential cache will be selected if it exists and contains tickets.

If the default credential cache does not exist, but the default client keytab does, the krb5 mechanism will try to acquire initial tickets for the first principal in the default client keytab.

If the krb5 mechanism acquires initial tickets using the default client keytab, the resulting tickets will be stored in the default cache or collection, and will be refreshed by future calls to `gss_acquire_cred` as they approach their expire time.

## 1.3 Acceptor names

A GSSAPI server application uses `gss_accept_sec_context` to establish a security context based on tokens provided by the client. The *acceptor\_cred\_handle* parameter determines what *keytab\_definition* entries may be authenticated to by the client, if the krb5 mechanism is used.

The simplest choice is to pass **GSS\_C\_NO\_CREDENTIAL** as the acceptor credential. In this case, clients may authenticate to any service principal in the default keytab (typically `FILE:/etc/krb5.keytab`, or the value of the **KRB5\_KTNAME** environment variable). This is the recommended approach if the server application has no specific requirements to the contrary.

A server may acquire an acceptor credential with `gss_acquire_cred` and a *cred\_usage* of **GSS\_C\_ACCEPT** or **GSS\_C\_BOTH**. If the *desired\_name* parameter is **GSS\_C\_NO\_NAME**, then clients will be allowed to authenticate to any service principal in the default keytab, just as if no acceptor credential was supplied.

If a server wishes to specify a *desired\_name* to `gss_acquire_cred`, the most common choice is a host-based name. If the host-based *desired\_name* contains just a *service*, then clients will be allowed to authenticate to any host-based service principal (that is, a principal of the form *service/hostname@REALM*) for the named service, regardless of hostname or realm, as long as it is present in the default keytab. If the input name contains both a *service* and a *hostname*, clients will be allowed to authenticate to any host-based principal for the named service and hostname, regardless of realm.

**Note:** If a *hostname* is specified, it will be canonicalized using forward name resolution, and possibly also using reverse name resolution depending on the value of the **rdns** variable in *libdefaults*.

---

**Note:** If the **ignore\_acceptor\_hostname** variable in *libdefaults* is enabled, then *hostname* will be ignored even if one is specified in the input name.

---

**Note:** In MIT krb5 versions prior to 1.10, and in Heimdal's implementation of the krb5 mechanism, an input name with just a *service* is treated like an input name of *service@localhostname*, where *localhostname* is the string returned by `gethostname()`.

---

If the *desired\_name* is a krb5 principal name or a local system name type which is mapped to a krb5 principal name, clients will only be allowed to authenticate to that principal in the default keytab.

## 1.4 Importing and exporting credentials

The following GSSAPI extensions can be used to import and export credentials (declared in `<gssapi/gssapi_ext.h>`):

```
OM_uint32 gss_export_cred(OM_uint32 *minor_status,
                          gss_cred_id_t cred_handle,
                          gss_buffer_t token);

OM_uint32 gss_import_cred(OM_uint32 *minor_status,
                          gss_buffer_t token,
                          gss_cred_id_t *cred_handle);
```

The first function serializes a GSSAPI credential handle into a buffer; the second unserializes a buffer into a GSSAPI credential handle. Serializing a credential does not destroy it. If any of the mechanisms used in *cred\_handle* do not support serialization, `gss_export_cred` will return **GSS\_S\_UNAVAILABLE**. As with other GSSAPI serialization functions, these extensions are only intended to work with a matching implementation on the other side; they do not serialize credentials in a standardized format.

A serialized credential may contain secret information such as ticket session keys. The serialization format does not protect this information from eavesdropping or tampering. The calling application must take care to protect the serialized credential when communicating it over an insecure channel or to an untrusted party.

A krb5 GSSAPI credential may contain references to a credential cache, a client keytab, an acceptor keytab, and a replay cache. These resources are normally serialized as references to their external locations (such as the filename of the credential cache). Because of this, a serialized krb5 credential can only be imported by a process with similar privileges to the exporter. A serialized credential should not be trusted if it originates from a source with lower privileges than the importer, as it may contain references to external credential cache, keytab, or replay cache resources not accessible to the originator.

An exception to the above rule applies when a krb5 GSSAPI credential refers to a memory credential cache, as is normally the case for delegated credentials received by `gss_accept_sec_context`. In this case, the contents of the credential cache are serialized, so that the resulting token may be imported even if the original memory credential cache no longer exists.

# DIFFERENCES BETWEEN HEIMDAL AND MIT KERBEROS API

|                                            |                                                                                                                                    |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>krb5_auth_con_getaddrs()</code>      | H5I: If either of the pointers to <code>local_addr</code> and <code>remote_addr</code> is not NULL, it is freed first              |
| <code>krb5_auth_con_setaddrs()</code>      | H5I: If either address is NULL, the previous address remains in place                                                              |
| <code>krb5_auth_con_setports()</code>      | H5I: Not implemented as of version 1.3.3                                                                                           |
| <code>krb5_auth_con_setrecvsubkey()</code> | H5I: If either port is NULL, the previous port remains in place                                                                    |
| <code>krb5_auth_con_setsendsubkey()</code> | H5I: Not implemented as of version 1.3.3                                                                                           |
| <code>krb5_cc_set_config()</code>          | MIT: Before version 1.10 it was assumed that the last argument <i>data</i> is ALWAYS non-zero                                      |
| <code>krb5_cccol_last_change_time()</code> | H5I takes 3 arguments: <code>krb5_context</code> context, <code>const char *type</code> , <code>krb5_timestamp *change_time</code> |
| <code>krb5_set_default_realm()</code>      | H5I: Caches the computed default realm context field. If the second argument is NULL, it is computed                               |

# INITIAL CREDENTIALS

Software that performs tasks such as logging users into a computer when they type their Kerberos password needs to get initial credentials (usually ticket granting tickets) from Kerberos. Such software shares some behavior with the *kinit(1)* program.

Whenever a program grants access to a resource (such as a local login session on a desktop computer) based on a user successfully getting initial Kerberos credentials, it must verify those credentials against a secure shared secret (e.g., a host keytab) to ensure that the user credentials actually originate from a legitimate KDC. Failure to perform this verification is a critical vulnerability, because a malicious user can execute the “Zanarotti attack”: the user constructs a fake response that appears to come from the legitimate KDC, but whose contents come from an attacker-controlled KDC.

Some applications read a Kerberos password over the network (ideally over a secure channel), which they then verify against the KDC. While this technique may be the only practical way to integrate Kerberos into some existing legacy systems, its use is contrary to the original design goals of Kerberos.

The function `krb5_get_init_creds_password()` will get initial credentials for a client using a password. An application that needs to verify the credentials can call `krb5_verify_init_creds()`. Here is an example of code to obtain and verify TGT credentials, given strings *princname* and *password* for the client principal name and password:

```
krb5_error_code ret;
krb5_creds creds;
krb5_principal client_princ = NULL;

memset(&creds, 0, sizeof(creds));
ret = krb5_parse_name(context, princname, &client_princ);
if (ret)
    goto cleanup;
ret = krb5_get_init_creds_password(context, &creds, client_princ,
                                password, NULL, NULL, 0, NULL, NULL);
if (ret)
    goto cleanup;
ret = krb5_verify_init_creds(context, &creds, NULL, NULL, NULL, NULL);

cleanup:
krb5_free_principal(context, client_princ);
krb5_free_cred_contents(context, &creds);
return ret;
```

## 3.1 Options for `get_init_creds`

The function `krb5_get_init_creds_password()` takes an options parameter (which can be a null pointer). Use the function `krb5_get_init_creds_opt_alloc()` to allocate an options structure, and `krb5_get_init_creds_opt_free()` to free it. For example:

```
krb5_error_code ret;
krb5_get_init_creds_opt *opt = NULL;
krb5_creds creds;

memset(&creds, 0, sizeof(creds));
ret = krb5_get_init_creds_opt_alloc(context, &opt);
if (ret)
    goto cleanup;
krb5_get_init_creds_opt_set_tkt_life(opt, 24 * 60 * 60);
ret = krb5_get_init_creds_password(context, &creds, client_princ,
                                   password, NULL, NULL, 0, NULL, opt);
if (ret)
    goto cleanup;

cleanup:
krb5_get_init_creds_opt_free(context, opt);
krb5_free_cred_contents(context, &creds);
return ret;
```

## 3.2 Getting anonymous credentials

As of release 1.8, it is possible to obtain fully anonymous or partially anonymous (realm-exposed) credentials, if the KDC supports it. The MIT KDC supports issuing fully anonymous credentials as of release 1.8 if configured appropriately (see *anonymous\_pkinit*), but does not support issuing realm-exposed anonymous credentials at this time.

To obtain fully anonymous credentials, call `krb5_get_init_creds_opt_set_anonymous()` on the options structure to set the anonymous flag, and specify a client principal with the KDC's realm and a single empty data component (the principal obtained by parsing *@realmname*). Authentication will take place using anonymous PKINIT; if successful, the client principal of the resulting tickets will be `WELLKNOWN/ANONYMOUS@WELLKNOWN:ANONYMOUS`. Here is an example:

```
krb5_get_init_creds_opt_set_anonymous(opt, 1);
ret = krb5_build_principal(context, &client_princ, strlen(myrealm),
                           myrealm, "", (char *)NULL);
if (ret)
    goto cleanup;
ret = krb5_get_init_creds_password(context, &creds, client_princ,
                                   password, NULL, NULL, 0, NULL, opt);
if (ret)
    goto cleanup;
```

To obtain realm-exposed anonymous credentials, set the anonymous flag on the options structure as above, but specify a normal client principal in order to prove membership in the realm. Authentication will take place as it normally does; if successful, the client principal of the resulting tickets will be `WELLKNOWN/ANONYMOUS@realmname`.

## 3.3 User interaction

Authenticating a user usually requires the entry of secret information, such as a password. A password can be supplied directly to `krb5_get_init_creds_password()` via the *password* parameter, or the application can supply prompter and/or responder callbacks instead. If callbacks are used, the user can also be queried for other secret information such as a PIN, informed of impending password expiration, or prompted to change a password which has expired.

### 3.3.1 Prompter callback

A prompter callback can be specified via the *prompter* and *data* parameters to `krb5_get_init_creds_password()`. The prompter will be invoked each time the `krb5` library has a question to ask or information to present. When the prompter callback is invoked, the *banner* argument (if not null) is intended to be displayed to the user, and the questions to be answered are specified in the *prompts* array. Each prompt contains a text question in the *prompt* field, a *hidden* bit to indicate whether the answer should be hidden from display, and a storage area for the answer in the *reply* field. The callback should fill in each question's `reply->data` with the answer, up to a maximum number of `reply->length` bytes, and then reset `reply->length` to the length of the answer.

A prompter callback can call `krb5_get_prompt_types()` to get an array of type constants corresponding to the prompts, to get programmatic information about the semantic meaning of the questions. `krb5_get_prompt_types()` may return a null pointer if no prompt type information is available.

Text-based applications can use a built-in text prompter implementation by supplying `krb5_prompter_posix()` as the *prompter* parameter and a null pointer as the *data* parameter. For example:

```
ret = krb5_get_init_creds_password(context, &creds, client_princ,
                                   NULL, krb5_prompter_posix, NULL, 0,
                                   NULL, NULL);
```

### 3.3.2 Responder callback

A responder callback can be specified through the *init\_creds* options using the `krb5_get_init_creds_opt_set_responder()` function. Responder callbacks can present a more sophisticated user interface for authentication secrets. The responder callback is usually invoked only once per authentication, with a list of questions produced by all of the allowed preauthentication mechanisms.

When the responder callback is invoked, the *rctx* argument can be accessed to obtain the list of questions and to answer them. The `krb5_responder_list_questions()` function retrieves an array of question types. For each question type, the `krb5_responder_get_challenge()` function retrieves additional information about the question, if applicable, and the `krb5_responder_set_answer()` function sets the answer.

Responder question types, challenges, and answers are UTF-8 strings. The question type is a well-known string; the meaning of the challenge and answer depend on the question type. If an application does not understand a question type, it cannot interpret the challenge or provide an answer. Failing to answer a question typically results in the prompter callback being used as a fallback.

#### Password question

The `KRB5_RESPONDER_QUESTION_PASSWORD` (or "password") question type requests the user's password. This question does not have a challenge, and the response is simply the password string.

## One-time password question

The `KRB5_RESPONDER_QUESTION_OTP` (or "otp") question type requests a choice among one-time password tokens and the PIN and value for the chosen token. The challenge and answer are JSON-encoded strings, but an application can use convenience functions to avoid doing any JSON processing itself.

The `krb5_responder_otp_get_challenge()` function decodes the challenge into a `krb5_responder_otp_challenge` structure. The `krb5_responder_otp_set_answer()` function selects one of the token information elements from the challenge and supplies the value and pin for that token.

## Example

Here is an example of using a responder callback:

```
static krb5_error_code
my_responder(krb5_context context, void *data,
             krb5_responder_context rctx)
{
    krb5_error_code ret;
    krb5_responder_otp_challenge *chl;

    if (krb5_responder_get_challenge(context, rctx,
                                     KRB5_RESPONDER_QUESTION_PASSWORD)) {
        ret = krb5_responder_set_answer(context, rctx,
                                         KRB5_RESPONDER_QUESTION_PASSWORD,
                                         "open sesame");

        if (ret)
            return ret;
    }
    ret = krb5_responder_otp_get_challenge(context, rctx, &chl);
    if (ret == 0 && chl != NULL) {
        ret = krb5_responder_otp_set_answer(context, rctx, 0, "1234",
                                           NULL);

        krb5_responder_otp_challenge_free(context, rctx, chl);
        if (ret)
            return ret;
    }
    return 0;
}

static krb5_error_code
get_creds(krb5_context context, krb5_principal client_princ)
{
    krb5_error_code ret;
    krb5_get_init_creds_opt *opt = NULL;
    krb5_creds creds;

    memset(&creds, 0, sizeof(creds));
    ret = krb5_get_init_creds_opt_alloc(context, &opt);
    if (ret)
        goto cleanup;
    ret = krb5_get_init_creds_opt_set_responder(context, opt, my_responder,
                                              NULL);

    if (ret)
        goto cleanup;
    ret = krb5_get_init_creds_password(context, &creds, client_princ,
                                      NULL, NULL, NULL, 0, NULL, opt);
}
```

```
cleanup:
    krb5_get_init_creds_opt_free(context, opt);
    krb5_free_cred_contents(context, &creds);
    return ret;
}
```

## 3.4 Verifying initial credentials

Use the function `krb5_verify_init_creds()` to verify initial credentials. It takes an options structure (which can be a null pointer). Use `krb5_verify_init_creds_opt_init()` to initialize the caller-allocated options structure, and `krb5_verify_init_creds_opt_set_ap_req_nofail()` to set the “nofail” option. For example:

```
krb5_verify_init_creds_opt vopt;

krb5_verify_init_creds_opt_init(&vopt);
krb5_verify_init_creds_opt_set_ap_req_nofail(&vopt, 1);
ret = krb5_verify_init_creds(context, &creds, NULL, NULL, NULL, &vopt);
```

The confusingly named “nofail” option, when set, means that the verification must actually succeed in order for `krb5_verify_init_creds()` to indicate success. The default state of this option (cleared) means that if there is no key material available to verify the user credentials, the verification will succeed anyway. (The default can be changed by a configuration file setting.)

This accommodates a use case where a large number of unkeyed shared desktop workstations need to allow users to log in using Kerberos. The security risks from this practice are mitigated by the absence of valuable state on the shared workstations—any valuable resources that the users would access reside on networked servers.

# PRINCIPAL MANIPULATION AND PARSING

## Kerberos principal structure

`krb5_principal_data`

`krb5_principal`

## Create and free principal

`krb5_build_principal()`

`krb5_build_principal_alloc_va()`

`krb5_build_principal_ext()`

`krb5_copy_principal()`

`krb5_free_principal()`

`krb5_cc_get_principal()`

## Comparing

`krb5_principal_compare()`

`krb5_principal_compare_flags()`

`krb5_principal_compare_any_realm()`

`krb5_sname_match()`

`krb5_sname_to_principal()`

## Parsing:

`krb5_parse_name()`

`krb5_parse_name_flags()`

`krb5_unparse_name()`

`krb5_unparse_name_flags()`

## Utilities:

`krb5_is_config_principal()`

`krb5_kuserok()`

`krb5_set_password()`

```
krb5_set_password_using_ccache()  
krb5_set_principal_realm()  
krb5_realm_compare()
```

# COMPLETE REFERENCE - API AND DATATYPES

## 5.1 krb5 API

### 5.1.1 Frequently used public interfaces

### 5.1.2 Rarely used public interfaces

### 5.1.3 Public interfaces that should not be called directly

### 5.1.4 Legacy convenience interfaces

### 5.1.5 Deprecated public interfaces

## 5.2 krb5 types and structures

### 5.2.1 Public

#### `krb5_int32`

#### `krb5_int32`

`krb5_int32` is a signed 32-bit integer type

#### `krb5_ui_4`

#### `krb5_ui_4`

`krb5_ui_4` is an unsigned 32-bit integer type.

### **5.2.2 Internal**

## **5.3 krb5 simple macros**

### **5.3.1 Public**

### **5.3.2 Deprecated macros**
